22 the manuscript.

Bile reflux gastritis

---

This is the author's manuscript of the article published in final edited form as:

McCabe IV, M. E., & Dilly, C. K. (2018). New Causes for the Old Problem of Bile Reflux Gastritis. *Clinical Gastroenterology and Hepatology*. <https://doi.org/10.1016/j.cgh.2018.02.034>

## 1 **Introduction.**

2 Bile reflux gastritis (also known as “duodenogastric reflux,” “biliary gastritis,” or “alkaline  
3 reflux gastritis”) occurs when there is retrograde movement of bile into the stomach, leading to  
4 clinical symptoms, endoscopic changes, and histologic features of a chemical (reactive) gastritis.  
5 While William Beaumont first observed bile reflux in a patient with a gastrocutaneous fistula in  
6 1833<sup>1</sup>, it was not until gastric surgery became routine in the late 1800s that the clinical  
7 importance of this problem was recognized. For nearly a century, this was thought to be a  
8 surgical disease, caused by resection or alteration of the pylorus. However, bile reflux gastritis is  
9 increasingly found in individuals without prior gastric surgery, a problem termed “primary  
10 biliary reflux.” Both surgical and pharmacologic interventions are used to treat this challenging  
11 condition.

## 13 **Description of the clinical problem**

14 Bile reflux gastritis can result from excess bile in the duodenum, lack of a pylorus as a barrier to  
15 retrograde flow, and/or decreased anterograde peristalsis of the stomach and duodenum. (See  
16 Figure 1) This can occur following gastric or biliary surgery or as primary biliary reflux. The  
17 most common predisposing surgeries are those that either remove, disrupt or bypass the pylorus,  
18 resulting in unopposed reflux of duodenal contents.

19  
20 Primary biliary reflux occurs in the absence of gastric surgery. Risk factors include gallbladder  
21 dysfunction and gastric or duodenal dysmotility.<sup>2</sup> Cholecystectomy predisposes to bile reflux  
22 due to loss of the gallbladder as a bile reservoir.<sup>3</sup> Biliary sphincterotomy leads to increased flow  
23 of bile through the sphincter of Oddi. Phase III of gastroduodenal motility (the migratory motor  
Bile reflux gastritis

1 complex) plays an important role, both in preventing duodenogastric reflux and in clearing the  
2 antral region of refluxed material. Individuals with bile reflux gastritis have been shown to have  
3 a decreased frequency of migratory motor complexes, suggesting that the gastritis might be  
4 related to a prolonged mucosal exposure to bile.<sup>7</sup>

5  
6 Recurrent and excessive exposure of gastric mucosa to bile reflux can lead to both endoscopic  
7 and histologic changes with or without symptoms. Evidence for this has been elegantly  
8 reviewed elsewhere.<sup>4</sup> Symptoms are vague and variable, but they can include abdominal pain,  
9 dyspepsia, nausea with bilious vomiting, weight loss or heartburn. Although the prevalence of  
10 bile reflux gastritis is unknown, the use of opioid pain medications, prevalence of type II  
11 diabetes mellitus, and performance of intestinal transplant surgeries are increasing, and all can be  
12 associated with gastroduodenal dysmotility.

#### 14 **Diagnosis**

15 The diagnosis of bile reflux gastritis can be challenging, particularly in those without surgical  
16 risk factors. Endoscopic and histologic findings may be non-specific, or not well recognized by  
17 clinicians. Although there are no universally accepted criteria, it is generally felt that evidence  
18 of duodenogastric reflux in conjunction with histologic changes of gastritis is sufficient to make  
19 the diagnosis. Modalities for establishing bile reflux include visualization of duodenogastric  
20 reflux or bile pooling in the stomach on endoscopy (see Figures 2 and 3), detection of bile salts  
21 in gastric fluid, measurement of bilirubin in the stomach using a fiber optic spectrophotometer or  
22 biliary radionuclide scanning showing radiotracer in the stomach; the latter three are not  
23 routinely performed in clinical practice.<sup>5,6</sup> Endoscopic findings most often include erythema of  
Bile reflux gastritis

1 the gastric mucosa and the presence of bile in the stomach (see Figure 4); thickened gastric folds,  
2 erosions, and gastric atrophy can also be seen.<sup>3,7</sup> Histologic examination shows features of a  
3 chemical gastritis including foveolar hyperplasia, edema, smooth muscle fibers in the lamina  
4 propria and paucity of acute or chronic inflammatory cells.<sup>8,9</sup> These features are similar to those  
5 seen in chronic non-steroidal anti-inflammatory drug use and other chemical injuries, so it is  
6 important to exclude this competing etiology.

## 8 **Management**

9 Management of bile reflux gastritis includes both medical and surgical options. Several medical  
10 therapies have been evaluated in uncontrolled or small controlled trials with variable results.  
11 Proton pump inhibitors are commonly used, although the mechanism of action is not clear. Bile  
12 acids are thought to cause damage due to their detergent properties; however, most precipitate at  
13 a low pH and cause more damage to gastric mucosa at a higher pH.<sup>4</sup> A randomized trial  
14 involving 60 post-cholecystectomy patients compared sucralfate (2 g twice daily) versus  
15 rabeprazole (20 mg daily) or no treatment.<sup>10</sup> In this study, epigastric pain was reduced by 45%  
16 in patients on sucralfate, by 30% in patients on rabeprazole and by 10% in the control group.  
17 Heartburn was reduced by 44% in the sucralfate group, 35% in the rabeprazole group and 15% in  
18 the control group. Endoscopic scores decreased in the treatment groups, although it was not  
19 clear whether the endoscopists were blinded. Another controlled trial for sucralfate found  
20 histologic but not symptomatic improvement. Ursodeoxycholic acid (UDCA) (1000 mg/day)  
21 was studied in a cohort of 11 patients with prior gastric surgery<sup>11</sup>. During treatment, the bile acid  
22 content in the stomach had a demonstrable change to UDCA. Five patients were treated for four  
23 weeks with placebo followed by four weeks of UDCA; these patients had no change in  
Bile reflux gastritis

1 symptoms with placebo but did improve after 4 weeks of UDCA. An additional seven patients  
2 were treated with UDCA followed by placebo; they had improvements on therapy but only 3 had  
3 recurrence of symptoms after the placebo period. Neither endoscopic appearance nor histology  
4 changed. Cholestyramine combined with alginates and Prostaglandin E2 have also been studied  
5 in small controlled trials but were ineffective. The role of pro-kinetic agents in the management  
6 of bile reflux gastritis has not been well studied. The goal of treatment is to relieve symptoms;  
7 although an increased risk of gastric adenocarcinoma has been theorized and suggested by  
8 animal models, this risk has not been demonstrated in humans.

9  
10 Surgical management of bile reflux aims to divert bile away from the stomach. These  
11 procedures are reserved for only severely symptomatic patients, generally where the reflux is  
12 caused by prior surgery. The most commonly utilized procedures include interposed  
13 isoperistaltic jejunal (Henley) loop, Braun enteroenterostomy and a roux-en-Y procedure. A  
14 roux-en-y choledochojejunostomy can be used to divert bile directly from the biliary tree after  
15 cholecystectomy.<sup>5</sup> These procedures are effective in relieving symptoms but can be complicated  
16 by stomal ulcerations, roux stasis syndrome, and bezoar formation.

17  
18 As a general treatment approach, the first step may be to stop any nonessential medications that  
19 might reduce gastroduodenal motility (see Figure 5). If medical therapy is necessary, given the  
20 lack of strong evidence for any particular therapy, we believe it is reasonable to start with a  
21 proton pump inhibitor. This is part of the treatment algorithm for dyspepsia, and it may treat  
22 etiologies of symptoms beyond bile reflux gastritis. If this is ineffective, ursodeoxycholic acid  
23 300mg three times daily may be tried. If symptomst persist, sucralfate 1-2g twice daily or a  
Bile reflux gastritis

1 proton pump inhibitor may be the next option. Combination therapy could be tried if individual  
2 therapies are ineffective. Finally, for severely symptomatic patients, particularly those whose  
3 reflux is caused by prior surgery, surgical diversion of bile can be considered.

#### 5 **Take-home messages**

- 6 • Bile reflux gastritis is a well-known complication of gastric surgery, particularly those that  
7 disrupt or bypass the pylorus.
- 8 • Primary biliary reflux is a more recently recognized problem that occurs in patients without  
9 gastric surgery and is related to excess bile in the duodenum (due to cholecystectomy,  
10 gallbladder dysmotility or sphincterotomy) or decreased gastric or duodenal motility.
- 11 • The diagnosis of bile reflux gastritis requires recognizing risk factors in symptomatic patients,  
12 followed by confirming the presence of bile in the stomach along with characteristic histologic  
13 findings.
- 14 • As the prevalence of conditions that alter gastrointestinal motility continues to increase, it is  
15 important that clinicians suspect and recognize this diagnosis.
- 16 • Treatment can be challenging but often includes a trial of medical therapy that may include  
17 ursodeoxycholic acid, sucralfate, or proton pump inhibitors.
- 18 • Patients with bile reflux gastritis related to prior surgery may benefit from surgical diversion of  
19 bile if medical treatments fail.

1 **Figure Legends.**

2 Figure 1 – Factors that can contribute to bile reflux gastritis. Gallbladder dyskinesia or surgical  
3 removal of the gallbladder lead to loss of the normal reservoir for storing bile. Sphincterotomy  
4 removes the barrier to bile flow into the duodenum. Surgical resection or alteration of the  
5 pylorus, such as in Billroth I or II or pyloroplasty, removes the barrier for retrograde bile flow  
6 into the stomach. Dysmotility of the stomach or duodenum can lead to retrograde movement or  
7 stasis of bile.
