PATIENT PERCEPTIONS REGARDING 
OUTPATIENT HIP AND KNEE ARTHROPLASTY

Abstract

Introduction: There has been increasing interest in outpatient total joint arthroplasty (TJA) in the orthopedic community, but how patients feel about outpatient TJA is unknown. The purpose of this study was to understand patient perspectives on hip and knee replacements performed in an outpatient setting rather than an inpatient hospital.

Methods: We surveyed 110 consecutive patients scheduled for primary TJA in an academic suburban arthroplasty practice regarding their existing knowledge and perceptions of outpatient TJA. Questionnaires were administered during preoperative clinic visits prior to any discussion of surgery location or length of stay and prior to the preoperative joint replacement education class. No mention of outpatient surgery or same day discharge occurred prior to completion of the questionnaire.

Results: Fifty-seven percent of respondents were female, and 42.7% were age 65 or older. Ninety-one percent of respondents had not previously had hip or knee replacement surgery. Very few patients expected same-day discharge (n = 3) or even a one night stay in the hospital (n = 17). 54% expected to stay in the hospital two or more nights. Only 54.5% of patients were aware that outpatient TJA is an option, with 55.3% of men and 31.7% of women reporting they were comfortable or very comfortable with outpatient TJA under circumstances in which someone was available to assist them at home ($p = 0.030$). Conversely, 61% and 72.8%, respectively, believed that faster recovery and decreased likelihood of hospital acquired infection are likely to be advantages of outpatient TJA. Interestingly, 51.9% of respondents felt ambulatory surgery centers are as safe as hospitals and 62.6% believed that home is the best place to recovery from TJA.
Conclusion: These observations suggest there is both opportunity and need for patient education regarding outpatient TJA. As outpatient hip and knee replacement becomes more common, it is essential that patients understand the ambulatory surgery process, the benefits and risks of same day discharge, and their role in a successful outpatient experience.

Keywords: outpatient knee arthroplasty, outpatient knee replacement, outpatient hip arthroplasty, outpatient hip replacement, patient perspectives
Introduction

There has been increasing interest in outpatient primary total hip (THA) and knee (TKA) arthroplasty. The interest in outpatient arthroplasty has been fueled by financial considerations including the ability to reduce costs within the episode of care, surgeon ownership in ambulatory surgery centers (ASC), and the ability to more easily control the surgical care environment in an ASC. Rapid recovery protocols have created a natural evolution from the inpatient to the outpatient setting. Outpatient total joint arthroplasty (TJA) has been successfully performed during the past decade, albeit for the most part by highly experienced surgeons with carefully selected patients. Success has been attributed to multidisciplinary care coordination, standardized perioperative protocols, discharge planning, and careful patient selection. Although the feasibility and safety of outpatient TJA has been studied from the vantage point of the surgeon, to the best of our knowledge, no studies have investigated patient perspectives on outpatient TJA. The purpose of the study was to understand patient thoughts and perspectives on hip and knee replacements performed in an outpatient setting.

Methods

With institutional review board approval, all patients of the primary author scheduled for primary THA or TKA in an academic suburban arthroplasty practice that performs outpatient TJA were offered a 16-question survey regarding their existing knowledge and perceptions of outpatient TJA (Appendix A). Questionnaires were administered during the first preoperative clinic visits occurring between 11/01/2015 and 04/31/2016 prior to any discussion of surgery location or length of stay expectations and prior to the preoperative joint replacement education.
class. No mention of outpatient surgery or same day discharge occurred prior to completion of
the questionnaire and the medical office did not contain any promotional material or information
regarding outpatient, same-day, or rapid discharge total joint replacement. Patients were
instructed not to put their names on the questionnaire to reduce potential bias associated with
surgeon knowledge of their responses.

Statistical Analysis

Minitab 17 (State College, PA) was used for data analysis. Pearson’s Chi-Square ($X^2$) test
was used to test independence among categorical variables with Fisher’s $p$ reported for 2 x 2
tables. Content analysis was used to categorize open-ended, qualitative responses to survey
questions 8 and 9.

Results

One hundred twelve patients were available for the study. Two declined the survey—one
due to visual impairment and inability to read the questionnaire and one due to inability to read
English. The final sample of 110 consecutive patient questionnaires represented a 98% response
rate. Fifty-seven percent of respondents were female, and 11.8% were age 50 or younger (n =
13), 45.5% were age 51 to 64 (n = 50), and 42.7% were age 65 or older (n = 47). Respondents
were scheduled for primary THA (32.7%), TKA (60.9%) or both (6.4%). Ninety-one percent of
respondents (98/108) had not previously had hip or knee replacement surgery. Patients who had
previously undergone THA or TKA had done so in an inpatient setting. Ten of 44 respondents
(22.7%) had taken care of someone after hip or knee replacement surgery or assisted a patient
who had outpatient TJA.

As shown in Table 1, only three respondents reported that they would expect to be
discharged on the same day as TJA surgery. The majority (64.6%) expected to be discharged in
1 to 2 days, but one in five (20.2%) thought they would be in the hospital three or more days following TJA. Expectations for discharge between less than 24 hours and 1 day did not differ based on patient sex ($X^2 = 0.539, p = 0.696$) or type of scheduled joint replacement ($X^2 = 1.441, p = 0.249$). (Age group could not be tested due to small cell counts.)

When asked “Have you ever heard of outpatient joint replacement where patients are discharged home the day of surgery or within 23 hours of surgery?” 54.5% (n = 60) responded yes. Awareness of outpatient joint replacement did not vary by sex ($X^2 = 1.479, p = 0.248$), age group ($X^2 = 0.297, p = 0.862$), or type of scheduled surgery ($X^2 = 0.077, p = 0.962$). Of the 60 patients who had heard about outpatient TJA, 53.3% (n = 32) had heard about it from family and friends, 18.3% (n = 11) from a primary care physician, 16.7% (n = 10) from an orthopedic surgeon, 3.3% (n = 2) from another patient, 1.7% (n = 1) from the internet, and 1.7% (n = 1) from television or radio. Five percent of respondents (n = 3) had heard about outpatient TJA from another source such as at work.

Survey respondents were asked “Assuming you have someone to assist you, how comfortable would you be being discharged the same day or within 23 hours of joint replacement surgery?” Overall, 13.0% (14/108) reported that they would be very comfortable, 21.3% (23/108) reported that they would be comfortable, 33.3% (36/108) said they were unsure, 12.0% (13/108) said they would be uncomfortable, and 20.4% (22/108) replied that they would be very uncomfortable with outpatient discharge following TJA. As shown in Figure 1, men were more comfortable with outpatient TJA surgery ($X^2 = 10.685, p = 0.030$) than women. Comfort level with outpatient surgery did not vary by age group ($X^2 = 6.538, p = 0.587$) or scheduled surgery type ($X^2 = 5.934, p = 0.204$).
As shown in Table 2, 70% to 82% of respondents believed that potential perceived limitations of outpatient TJA – including limited implant types, use of the direct anterior approach to THA, increased complications, difficult pain control, challenges regaining mobility, and challenging recovering from anesthesia – were unlikely. Sixty-one percent and 72.8%, respectively, believed that faster recovery than expected and decreased likelihood of hospital acquired infection were likely to be advantages of outpatient TJA (Table 2). Perceptions of faster recovery did not vary by patient sex ($X^2 = 1.316, p = 0.303$) or scheduled surgery type ($X^2 = 2.868, p = 0.238$), but significantly more patients age 50 or younger (83.3%) vs. 50% of those age 51 to 64 and 68.3% of those age 65 or older thought faster recovery was a likely advantage of outpatient TJA ($X^2 = 5.889, p = 0.053$). Significantly more women (80.7%) than men (62.2%) believed that outpatient surgery would reduce the likelihood of hospital acquired infection ($X^2 = 4.312, p = 0.046$). Perspectives on hospital acquired infection in general did not vary based on age group ($X^2 = 0.106, p = 0.949$) or type of scheduled surgery ($X^2 = 1.393, p = 0.498$).

Overall, 36.8% (39/106) of respondents felt it was safer to have TJA surgery in a hospital, 11.3% (12/106) felt that ASCs are safer, and 51.9% (55/106) felt that hospitals and ASCs are equally safe (Figure 2). This observation did not vary by patient sex ($X^2 = 0.926, p = 0.629$) or scheduled surgery type ($X^2 = 0.719, p = 0.698$). Reflecting a statistical trend, 20% of respondents between the ages of 51 and 64 compared to none of those age 50 or younger and 4.7% of those age 65 or older reported that ASCs are safer than hospitals ($X^2 = 8.132, p = 0.087$).

Most respondents (62.6%, 67/107) believed it would be better to recover from joint replacement surgery at home. Twenty-three percent (25/107) believed recovering in the hospital would be better, and 14% (15/107) did not think that recovery would be better in one place or the other (Figure 3). Perceptions of recovery at home or in the hospital did not vary based on patient
Patients were asked about optimal conditions for outpatient TJA, including whether it is appropriate for partial or total joint replacement and what makes someone a good or a poor candidate for outpatient TJA. Thirty-nine percent of respondents (40/102) reported that outpatient surgery is most appropriate for partial joint replacement, 5% (5/102) felt it was most appropriate for total joint replacement, and 55.9% (57/102) felt it was appropriate for both partial and total joint replacement. Table 3 presents responses to open-ended questions asking what factors or characteristics would make someone a good or a poor candidate for outpatient joint replacement surgery. Respondents uniformly identified the presence or absence of overall good health, care support and/or a safe home environment, positive attitude/outlook/motivation, pain management, obesity, and age as important contributing factors.

Discussion

Outpatient TJA is on the rise in the United States due to increasing emphasis on reducing the cost of healthcare and the ability for surgeons to more readily control surgical care in ASCs. The increase in outpatient TJA has been possible due to significant advances in the perioperative management of joint replacement patients including multidisciplinary care coordination, standardized perioperative protocols, discharge planning, and careful patient selection.[2-4, 7, 13, 15, 16] To date, however, patient knowledge of and opinions on outpatient hip and knee replacement are unknown. This descriptive study was conducted to enhance understanding of patient views on TJA performed in an outpatient setting rather than in an inpatient hospital.

In our convenience sample of consecutive patients scheduled for hip and/or knee replacement, 54% expected to stay in the hospital two or more days following surgery, only three
respondents reported they would not expect to stay in the hospital overnight, and only 17
reported that they expected to be discharged after one night in the hospital, suggesting that same
day and early discharge were far from common patient expectations. Slightly more than half of
respondents had heard of outpatient joint replacement defined as being discharged the day of
surgery or within 23 hours of surgery. Awareness of outpatient joint replacement did not vary
based on patient sex, age group (50 or younger, 51 to 64, and 65 or older), or scheduled surgery
type (THA, TKA, or both). Most respondents had heard about outpatient TJA from family or
friends (53.3%). Thirty-five percent had heard about it from a primary care physician or
orthopedic surgeon.

Only 11.7% of women compared to 31.9% of men reported that they were very
comfortable being discharged the same day or within 23 hours of joint replacement surgery, a
statistically different observation ($p = 0.030$). Comfort level with outpatient TJA did not vary by
age group or type of scheduled TJA. The majority of patients reported that potential perceived
limitations of outpatient joint replacement – including limited implant types, use of the direct
anterior approach to THA, increased complications, difficult pain control, challenges regaining
mobility, and challenging recovering from anesthesia – were unlikely. Conversely, a majority
believed that faster recovery than expected – especially those age 50 or younger ($p = 0.053$) --
and decreased likelihood of hospital acquired infection – especially women ($p = 0.046$) -- were
likely to be advantages of outpatient TJA. Slightly more than half of all respondents felt that
total joint replacement was equally safe in hospitals and ASCs. Independent of sex, age group,
and type of scheduled surgery, two out of three respondents believed it would be better to
recover from joint replacement at home rather than in the hospital. Respondents identified the
presence or absence of overall good health, care support and/or a safe home environment,
positive attitude/outlook/motivation, pain management, obesity, and age as factors which would
determine whether someone is a good or a poor candidate for outpatient TJA.

Our study is limited by the use of a convenience sample of patients scheduled for total
hip and/or knee replacement with a single surgeon in a single arthroplasty practice.
Nevertheless, the study was conducted to acquire the first, initial insight into patient perspectives
on outpatient TJA. It is hoped that it will be instigate similar inquiries in diverse TJA settings,
especially those offering outpatient hip and knee replacement surgery. As outpatient hip and
knee replacement becomes more common, it will be important to ensure that patients understand
the ambulatory surgery process, the benefits and risks of same day discharge, and their role in a
successful outpatient experience. Fulfillment of these objectives should be predicated on solid
patient understanding of outpatient TJA. Hunt et al.[21] observed that patients may not overtly
state concerns about early discharge following THA due, in part, to their role as patients
dependent upon the expertise of healthcare providers. In addition, patient expectations regarding
length of hospital stay may reflect unstated needs and motivations such as concerns about
burdening family members with their care. These represent important additional areas for
research-based understanding and clinical communication.

Overall, our observations suggest that there is ample opportunity and need for patient
education on the topic of outpatient joint replacement. Prior to preoperative education, very few
patients scheduled for TJA expected zero nights, or even a one night stay, in the hospital. Two
or more nights in the hospital was the predominant expectation. One-half of patients were not
even aware that outpatient TJA is an option. Only 1 in two male patients and 3 in 10 female
patients reported being comfortable or very comfortable with outpatient joint replacement under
circumstances in which someone was available to assist them at home, despite the fact that most
patients felt ASCs were as safe as hospitals and that home is the best place to recovery from TJA.

PATIENT VIEWS ON OUTPATIENT JOINT REPLACEMENT

1. Gender (circle one): Male Female

2. Age (circle one): 50 or less 51-64 65 or greater

3. Are you here today for a hip or a knee problem? Hip Knee Both

4. In general, how many nights would you expect to stay in the hospital after joint replacement surgery? ___________

5. Have you ever heard of outpatient joint replacement where patients are discharged home the day of surgery or within 23 hours of surgery (circle one answer)?
   Yes (please go to question 6) No (please go to question 7)

6. Where or from whom did you hear about outpatient joint replacement? (check all that apply):
   ___Family or friends ___Newspaper
   ___Another patient ___Orthopaedic surgeon
   ___Your family or primary care doctor ___Internet
   ___TV or radio ___Other (please specify): ________________________________________________________________

7. Assuming you have someone to assist you, how comfortable would you be being discharged the same day or within 23 hours of joint replacement surgery (circle one answer)?
   Very uncomfortable Uncomfortable Unsure Comfortable Very comfortable

8. In your opinion, what factors or characteristics would make someone a good candidate for outpatient joint replacement surgery?
   _________________________________________________________________________________________________
   _________________________________________________________________________________________________
   _________________________________________________________________________________________________

9. What would make someone a poor candidate for outpatient joint replacement?
   _________________________________________________________________________________________________
   _________________________________________________________________________________________________
   _________________________________________________________________________________________________

11. Do you think that outpatient surgery would be appropriate for partial joint replacements, total joint replacements, or both (circle one answer)?

   Partial joint replacements  Total joint replacements  Both

12. In your view, is it safer to have surgery in an ambulatory surgery center (ASC) or in a hospital?

   ASC's are safer  Hospitals are safer  They are equally safe

13. In general, do you believe it would be better for you to recover from joint replacement at home or in the hospital?

   At Home  In the Hospital  No difference

14. Have you had hip or knee replacement surgery (circle one answer)?

   Yes – If yes, was it inpatient or outpatient surgery (circle answer)?
   No

15. Have you taken care of someone after they had hip or knee replacement surgery (circle one answer)?

   Yes – If yes, did they have outpatient surgery (circle answer)?  Yes  No
   No
