Although the attention of the world and the global health community specifically is deservedly focused on the COVID-19 pandemic, other determinants of health continue to have large impacts and may also interact with COVID-19. Air pollution is one crucial example. Established evidence from other respiratory viruses and emerging evidence for COVID-19 specifically indicates that air pollution alters respiratory defense mechanisms leading to worsened infection severity. Air pollution also contributes to comorbidities that are known to worsen outcomes among those infected with COVID-19, and air pollution may also enhance infection transmission due to its impact on more frequent coughing. Yet despite the massive disruption of the COVID-19 pandemic, there are reasons for optimism: broad societal lockdowns have shown us a glimpse of what a future with strong air pollution measures could yield. Thus, the urgency to combat air pollution is not diminished, but instead heightened in the context of the pandemic.

PROBLEM

Air pollution is a major contributor to the global burden of disease, with an estimated 12% of all deaths in 2019 attributable to outdoor and household air pollution. While the impacts of air pollution on respiratory diseases is widely recognized, 50% of the estimated 6.7 million deaths attributable to air pollution in 2019 are due to cardiovascular diseases. Globally, nearly 20% of cardiovascular disease deaths were attributable to air pollution. Further, air pollution was the 4th highest ranking risk factor for mortality, with more attributable deaths than high LDL cholesterol, high body-mass index, physical inactivity, or alcohol use (Figure 1).

Globally air pollution contributes to an average loss of life expectancy of 20 months, nearly as high as that for tobacco use (22 months), with losses of 2.5 years in South Asia. Despite increasing awareness of the impact of air pollution on population health, appreciation of air pollution as a modifiable risk factor is still limited among health care providers. With this joint opinion, and in accordance with the Sustainable Development Goals, the WHF, AHA, ESC and ACC call for action in research and policy development at a global scale. Further, we aim to generate awareness about the impact of air pollution on cardiovascular disease as a means toward reaching the World Heart Federation Goal of a 25% reduction in premature cardiovascular mortality by 2025.

AIR POLLUTION AND CVD: EVIDENCE

Air pollution is a complex and dynamic mixture of numerous compounds in gaseous and particle form, originating from diverse sources, subject to atmospheric transformation and varying over space and time. Three common air pollutants,
particulate matter (PM), ozone and nitrogen dioxide (NO2), are the focus of most monitoring programs, communication efforts, health impact assessments, and regulatory efforts.

Evidence for impacts on cardiovascular disease is most consistent for particulate matter, which is responsible for the vast majority of the disease burden via its impacts on ischemic heart disease, stroke, as well as lung cancer, COPD, lower respiratory infections, Type 2 diabetes, pregnancy outcomes and related infant mortality.

Time series studies conducted in hundreds of urban areas globally indicate a consistent association between short-term variability in particulate matter and cardiovascular disease deaths, while large cohort studies from both high and lower income settings demonstrate increased cardiovascular disease incidence and mortality in association with PM levels. Further, particulate matter air pollution has been associated with progression of atherosclerosis. Ozone is mainly associated with exacerbation of respiratory disease, with COPD incidence and mortality and with metabolic effects. NO2 is often used as an indicator of traffic-related air pollution. Chronic exposure to NO2 is associated with incident childhood asthma while short-term variability is associated with exacerbation of asthma and increased daily mortality counts.

A scientific statement from the American Heart Association provides a detailed description of the pathophysiologic mechanisms through which particulate matter triggers cardiovascular events. Figure 2 summarises the likely dominant pathways including activation of oxidative stress/inflammation and autonomic imbalance, as well as translocation of components of the particulate matter mixture (ultrafine particles or specific constituents) into the systemic circulation. In turn, these alterations promote both subclinical cardiovascular disease (myocardial remodelling, atherosclerosis progression, systemic and pulmonary hypertension, enhanced vasoconstriction and coagulation) and thrombotic and nonthrombotic acute cardiovascular events (acute coronary syndromes, decompensated heart failure, stroke, life-threatening arrhythmias). The AHA statement suggests the existing evidence is consistent with a causal relationship between PM exposure and cardiovascular morbidity and mortality.

More recently, the European Society of Cardiology expert position paper updated the observational and mechanistic evidence and identified air pollution as one of several major modifiable risk factors relevant to the prevention and management of cardiovascular disease. The ESC paper identified a need for additional research regarding the role of air pollution in relation to hypertension and incident heart failure. This position paper also highlighted the role of health professionals, including cardiologists, in counseling their patients on the risks of air pollution while also supporting educational and policy initiatives to reduce air pollution exposure.
OPPORTUNITY FOR GLOBAL IMPACT

The threats posed by air pollution are substantial. Approximately 7 billion persons (92% of the global population), live in areas where the WHO Annual Air Quality Guideline for PM$_{2.5}$ is exceeded and 3.6 billion people (47% of the global population) are exposed to household air pollution from the use of solid fuels for cooking. Recent research also indicates that air pollution impacts cardiovascular health even at very low levels below current WHO guidelines and most national standards. Further, climate change is leading to increased frequency and severity of wildfires, which leads to large smoke episodes and associated health impacts affecting major metropolitan areas.

Despite these challenges, given its near-ubiquitous exposure, air pollution reduction offers a powerful opportunity to equitably reduce cardiovascular disease. Experience also indicates a clear path forward. In the United States, reductions in PM concentrations resulting from a diverse array of regulatory actions and technologies were responsible for up to 15% of the increase in US life expectancy observed over the past several decades. Similarly, programs such as India’s Pradhan Mantri Ujjwala Yojana have made clean cooking fuels accessible to millions of households, helping to reduce inequalities in noncommunicable diseases.

ADDRESSING THE CHALLENGE: THE ROLE OF CARDIAC ORGANIZATIONS, SOCIETIES, AND FOUNDATIONS

The WHF, ACC, AHA, and ESC are united in our commitment to research, advocacy, and education to reduce the impacts of air pollution on cardiovascular health. Specifically, we will advocate for further research on cardiovascular disease and air quality, disseminating findings to our memberships and via other activities, such as World Heart Day. We will also work to educate and raise awareness among health care providers on the importance of reducing...
air pollution and the cardiovascular benefits of air pollution mitigation. We will work with senior decision-makers in national, regional and global governmental institutions to make air pollution–related heart disease a priority and to identify interventions to reduce air pollution and its impact on noncommunicable diseases. Finally, we will work with our members to increase the development and use of clinical guidelines on air pollution and cardiovascular disease to ensure clinicians are educated on the topic. In addition, we will strive to provide presentations on the links between air pollution and cardiovascular disease at our respective congresses, engagements, and events.

Structural actions to mitigate pollution emissions are ultimately necessary to reduce harmful exposures. Before mitigation is achieved, health care providers can play several important roles. First, clinicians can advocate for air pollution mitigation as a health measure. Second, clinicians can provide patients with personal measures to reduce exposures and associated risk at the individual level. For example, use of room air filtration can provide substantial improvements in PM levels within residences, schools and workplaces, with some evidence indicating improvements in blood pressure and measures of inflammation. Third, health care providers can integrate air pollution into disease management approaches. Communication tools such as various air quality indices focused on short-term variation in air quality can help patients adjust activities when air quality is poor. Detailed air pollution maps that provide information on long-term exposures and their impacts at neighborhood scales can also be used to target CVD treatment, exposure reduction, and efforts to address other behavioural risks contributing to CVD in those living in locations with highest exposures. Finally, the health sector as a whole, which bears the impact of air pollution, can provide much-needed support for ministries of environment, energy, and transportation, which are traditionally responsible for mitigation efforts.
