The rapidly expanding novel coronavirus disease 2019 (COVID-19) pandemic, caused by severe acute respiratory syndrome coronavirus 2, has challenged the medical community to an unprecedented degree. Physicians and health care workers are at added risk of exposure and infection during the course of patient care. Because of the rapid spread of this disease through respiratory droplets, health care workers who come in close contact with the upper aerodigestive tract during diagnostic and therapeutic procedures, such as otolaryngologists–head and neck surgeons, are particularly at risk. A set of safety recommendations was created based on a review of the literature and communications with physicians with firsthand knowledge of safety procedures during the COVID-19 pandemic.

A high number of health care workers were infected during the first phase of the pandemic in the city of Wuhan, China. Subsequently, by adopting strict safety precautions, other regions were able to achieve high levels of safety for health care workers without jeopardizing the care of patients. The most common procedures related to the examination and treatment of upper aerodigestive tract diseases were reviewed. Each category was reviewed based on the potential risk imposed to health care workers. Specific recommendations were made based on the literature, when available, or consensus best practices. Specific safety recommendations were made for performing tracheostomy in patients with COVID-19.

Preserving a highly skilled health care workforce is a top priority for any community and health care system. Based on the experience of health care systems in Asia and Europe, by following strict safety guidelines, the risk of exposure and infection of health care workers could be greatly reduced while providing high levels of care. The provided recommendations, which may evolve over time, could be used as broad guidance for all health care workers who are involved in the care of patients with COVID-19.

The preservation of this highly skilled, limited workforce should be a top priority of health care officials and policy makers. At the time of this writing, to our knowledge, no unified, widely agreed-on protocols exist on how to perform a routine examination of the head and neck; office-based rigid and flexible endoscopy of the nose, sinuses, and larynx; tracheostomy; and other common operations. Some health authorities and societies have developed separate guidelines. The preservation of this highly skilled, limited workforce should be a top priority of health care officials and policy makers. At the time of this writing, to our knowledge, no unified, widely agreed-on protocols exist on how to perform a routine examination of the head and neck; office-based rigid and flexible endoscopy of the nose, sinuses, and larynx; tracheostomy; and other common operations. Some health authorities and societies have developed separate guidelines.

This article was prepared in consultation with otolaryngologists–head and neck surgeons and other health care workers in the US, Asia, and Europe, applying existing guidance from the infection control specialty to physicians potentially at risk from exposure to the virus.
Head and neck of infected patients. As the available information evolves, we expect to modify these guidelines. We expect that each health authority or organization will make specific decisions appropriate to their community. These recommendations have been developed to give broad guidance to practitioners. Per the US Centers for Medicare & Medicaid Services, the following factors should be considered when determining whether a planned examination or surgical procedure should proceed: current and projected COVID-19 cases in the facility and region; supply of personal protective equipment (PPE), beds, ventilators, and staff in the facility and system; health and age of the patients, especially given the risks of SARS-CoV-2 infection during recovery; and urgency of the procedure.6 Here, we highlight common procedures that should be considered and provide a framework on which to base decisions using the best available evidence. As this is a highly fluid situation, it is likely that these recommendations will change based on emerging evidence, the infection burden, availability of the health care workforce, and medical infrastructure.

General Considerations

General Care of Otolaryngologic Patients

Head and neck examinations are considered high risk in patients with suspected or confirmed COVID-19; therefore, we recommend the following guidelines. Depending on the current circumstances of the local setting, such as the rate of community spread and case doubling time, routine, nonurgent appointments should be postponed to limit the chance of SARS-CoV-2 infection of patients or health care workers during their visit to the facility. This may include postponing appointments for patients with benign disease (eg, benign salivary or thyroid tumors, hyperparathyroidism) or patients undergoing routine surveillance visits after treatment for head and neck cancer. In all instances, patients should be queried by telephone about any new or concerning signs or symptoms that may suggest disease recurrence and/or pending issues, such as severe dysphagia or airway compromise, as well as current symptoms suggestive of COVID-19. Patients thought to be at risk for significant negative outcomes without evaluation should be offered an in-person clinic visit. Those with symptoms suggesting possible COVID-19 should be directed to the appropriate self-care or triage mechanism. The use of telephone, video, or telemedicine visits should be considered to maintain relationships with patients and to support assessments that can be made without an in-person physical examination. Only patients who need a thorough head and neck examination should be seen in person.

Use of Powered Air-Purifying Respirators vs N95 Masks

In the literature, conflicting practices can be seen regarding the use of N95 masks and tight-fitting goggles or the use of powered air-purifying respirators (PAPRs).5,7 PAPRs reduce the risk of exposure more than N95 masks, but how much more they reduce the risk depends on the airflow setting. The assigned protection factor range is 25 to 1000 for PAPRs and 10 for N95 masks.8 The most common concern about using PAPRs is their effect on the sterile field during surgery, as they do not filter the discharged air, but there are few data on the infection risk compared with other methods or in combination with the use of a mask. Nearly as important, they are also cumbersome to use. They can limit visibility if they fog up, make using a headlight impossible, and, if the hooded type is used, render the use of a stethoscope impossible. Donning and doffing are opportunities for self-exposure. However, ill-fitting N95 masks also increase the risk of exposure and thus carry their own disadvantages. Decisions about which protection to use may depend on the settings, risks, and logistics.9 Practicing the planned tasks in the use of PAPRs if they are to be used is important.

The Otolaryngology–Head and Neck Physical Examination and Associated Procedures

General Examination

Head and neck examination that will include the mucous membranes should be performed by maintaining the suggested level of precaution (Table). The examination preferably should be performed in a separate room away from other patients, and only the necessary personnel should be present. The examination should be performed by the most experienced person present and might be a more focused assessment, based on the judgment of the examining physician. Proper doffing and disposal of PPE are of utmost importance.

Endoscopic Examinations of the Mucosa of the Head and Neck

Endoscopic examinations of the nose, sinuses, oropharynx, hypopharynx, and larynx are among the most common head and neck diagnostic procedures and are routinely performed by a wide variety of practitioners and trainees. They are considered aerosol-generating procedures.10 Moreover, the nose and nasopharynx have been shown to be reservoirs for high concentrations of the SARS-CoV-2 virus,11 and after manipulation, viral particles have been shown to be airborne for 3 hours or more.12 Therefore, we recommend the same precautions be adopted for mucosal surface endoscopic examinations of the head and neck as for other aerosol-generating procedures.

Examinations should be limited to patients who have a clear indication and need. Again, the examination should be performed by the most experienced personnel available in an expedient fashion. Routine or lower-priority examinations should be deferred during the pandemic. Patients should be placed in private rooms with negative pressure if available, and the use of PPE should follow the guidance of the Table. Specific recommendations additionally include the following:

1. In awake patients, adequate topical preparation to make the examination more comfortable is important. However, use of sprays should be avoided. Carefully placed pledges should be used to provide decongestion and anesthesia.

2. Topical anesthesia for any office-based intervention of the larynx under the guidance of a laryngoscope or strobolaryngoscope is performed through application of a spray. This is considered high risk; therefore, office-based biopsy, injection, laser, or other procedures should be delayed if possible.

3. If a video screen is available to project the examination, it should be used to keep the patient’s and health care worker’s faces apart.

4. Disposable endoscopes may be considered.

5. After completion of the examination, the endoscope must be appropriately handled. The endoscope should not be removed from the examination room without a protective cover.

Abbreviations: PAPR, powered air-purifying respirator; SARS, severe acute respiratory syndrome; SARS-CoV-2, SARS coronavirus 2.

Adapted and updated with permission from Stanford Health Care. Recommendations are subject to change as more data become available.

b If patient is immune compromised (receiving active chemotherapy, radiotherapy, or immunotherapy; <1 y after solid organ transplant; receiving chronic immunosuppression therapy; pregnant), both the patient and clinician should wear a surgical mask unless the patient is high risk. Clinicians and staff should wear a face shield over a surgical mask to allow reuse of the mask.

Commonly Performed Otolaryngology Procedures

**Procedures Commonly Performed Outside the Operating Room**

These inpatient, emergency department, and outpatient otolaryngology procedures should be handled differently during the pandemic. Adequate education of health care workers is essential. The following are examples of procedures that in this setting are considered high risk:
- Routine suctioning of patients with a tracheotomy.
- Nasal packing placement, removal, or manipulation.
- Drainage of peritonsillar abscesses. Consider avoiding through the use of antibiotic management or needle drainage instead of open drainage.
- Attempted foreign body removal. Deferring may not be possible.

If the location is such that it will be particularly challenging to access in an awake patient or if the individual is particularly intolerant of manipulation, performing the removal under general anesthesia may be necessary.

**Operative Procedures—General Considerations**

A number of head and neck, otolaryngologic, and oral surgery procedures are high risk owing to exposure of airway and mucosal surfaces and the possibility of generating aerosols. During the pandemic, based on the guidelines of national and state authorities, all elective procedures that can be safely postponed should be delayed. If an operative procedure involving the mucosa of the head and neck is planned, the following considerations are recommended.

**COVID-19 Status**

If possible, determine the COVID-19 status of the patient beforehand. If a patient tests positive, a careful assessment of risk to the patient and health care workers should be performed by a multidisciplinary team before the operation is recommended. Operating on mucosal surfaces in a patient who is actively infected generates a great risk for the entire operating room and recovery units and may compromise the patient’s ability to recover from the infection.

**Operating Room Setting**

High-risk operations or operations in patients with known COVID-19 should be performed in a designated operating room with negative pressures. Unprotected health care personnel should not be allowed in a room where an aerosol-generating procedure is being or has been conducted. If a patient is known or suspected to have COVID-19, appropriate PPE must be worn by all.
High-Risk Procedures
Considering the high viral titers in nasal mucosal, oral, pharyngeal, and pulmonary secretions, any operation that involves these surfaces is high risk to the entire operating room personnel. To our knowledge, bloodborne transmission has not been documented, but aerosolization of blood through the use of energy devices used for control of bleeding and in dissection has been documented. These procedures should be considered higher risk. This includes the use of powered devices (eg, drills, microdebriders, saws) or ultrasonic shears, such as the Harmonic scalpel (Ethicon) or Thunderbeat scalpel (Olympus).

If a high-risk operation is indicated during the pandemic in a SARS-CoV-2-negative patient or a patient without symptoms or contact, appropriate PPE for all operating room staff is strongly recommended. Observed levels of community disease will not reflect the full prevalence.

Intubation and Extubation
In all operations, coordination with the anesthesia team is critical. It is advisable that during intubation, all nonessential staff leave the room and only return after the airway is secured. Additionally, all nonessential staff should be out of the room during extubation. Anybody who is present should maintain appropriate PPE. In some centers, an interval equivalent to known air exchange times for that operating room is practiced before other personnel are allowed to enter. Jet ventilation procedures pose a particularly high risk and should be performed only under absolute necessity and with appropriate PPE, preferably in a negative-pressure room.

Patient Transport
Adequate protection during the transfer of SARS-CoV-2-positive patients or patients of unknown infection status after a high-risk procedure is critical. Clear protocols should be established with the nursing staff, recovery unit personnel, anesthesia department, and infection control personnel. Nonintubated patients could be transferred while wearing a surgical mask (not an N95 mask) if tolerated. If oxygen is required, it can be administered by face mask over the surgical mask. Intubated patients should be transported with an intensive care unit ventilator (dry circuit, filter in place) and not with a bag-valve mask, which breaks the closed circuit. Appropriate PPE should be maintained by all health care workers participating in the transfer.

Operative Procedures—Specific Procedures and Scenarios
Endoscopic Sinonasal and Skull Base Surgery
Endoscopic nasal operations, including sinus surgery and transsphenoidal pituitary surgery, are very high-risk procedures. In general, these procedures should be postponed in patients with COVID-19 or those who cannot be tested. In negative patients, PPE for all operating room staff is recommended as per the Table.55

Thyroidectomy and Neck Procedures
Procedures that do not expose mucosal surfaces are lower risk, with the caveat that the use of energy devices can result in aerosolization of the virus from the bloodstream or other gastrointestinal secretions. Patients with COVID-19 are likely to have the virus in their bloodstream and feces, based on the experience with SARS, which is also caused by a coronavirus.56,57

Ear Surgery
It is not known if the respiratory mucosa lining the middle ear and mastoid air cell system is involved in COVID-19. But because the rest of the airway is involved, it appears likely that the lining of the eustachian tube, middle ear, and mastoid air cell system are all contaminated.18,19 Drilling through the mastoid creates droplets and aerosols in significant clouds that, if the virus is present, could risk infecting everyone in the operating room environment. As contaminated mists harbor viable virus for several hours, especially in enclosed spaces, caution is warranted. Mastoidectomy therefore is considered a high-risk procedure. Ideally, any patient undergoing any ear surgery should be tested for COVID-19 preoperatively. If a patient is positive, surgery should be delayed until the patient has cleared the disease.

Management of Facial Trauma
Management of trauma patients should be led by the trauma management team. Physicians who are called to assess trauma patients or perform specific procedures in areas of high community spread should be equipped with adequate PPE based on the trauma center policies. After following the trauma triage protocol, if assessment and treatment of facial trauma is needed, our recommendation is to treat patients of unknown COVID-19 status as COVID-19 positive. Lacerations that involve mucosal surfaces should be treated as high risk. For injuries that require operative intervention (for example, reduction of fractures), the infection status of the patient should be confirmed first and then definitive treatment initiated if at all possible. In areas with significant shortage of medical capacity and personnel, nonoperative approaches should be considered as much as medically acceptable.

Tracheostomy
Performing tracheostomy on patients with suspected or confirmed COVID-19 imposes unique challenges on not only otolaryngologists-head and neck surgeons but the entire health care team.20 In nonemergency situations, all cases should be reviewed by a multidisciplinary team, and the risks vs benefits of the procedure for the patient and the entire health care team should be carefully assessed. Additionally, a detailed postprocedure care plan should be established to ascertain the protection of other patients and health care workers. The accompanying article by Tay et al60 outlines many of these considerations. In general, most tracheostomy procedures should be avoided or delayed (even beyond 14 days) because of the high infectious risks of the procedure and subsequent care until such time as the acute phase of infection has passed, when the likelihood of recovery is high, and when ventilator weaning has become the primary goal of care. Avoiding early tracheostomy in patients with COVID-19 is suggested because of the higher viral load that may be present at this time. In addition, early tracheostomy was not found to be associated with improved mortality or reduced length of intensive care unit stay in a randomized clinical trial of patients on mechanical ventilation.71

We suggest the following additional guidelines:
1. Select the patients carefully. If the tracheostomy is assessed as difficult because of anatomy, history, comorbidities, or other factors, consider postponing the procedure.
2. Consideration may be given to percutaneous dilatational tracheostomy if the patient’s anatomy and proceduralist expertise
allow it to be done safely with minimal or no bronchoscopy, endotracheal suctioning, and disruption of the ventilator circuit.

3. Provide adequate sedation including paralysis to eliminate the risk of coughing during the procedure. Ventilation should be paused (apnea) at end-expiration when the trachea is entered and any time the ventilation circuit is disconnected.

4. Choose a nonfenestrated, cuffed, tracheostomy tube on the smaller side to make the tracheostomy hole smaller overall (Shiley size 6 for both men and women is adequate). Keep the cuff inflated to limit the spread of virus through the upper airway.

5. Perform tracheostomy suctioning using a closed suction system with a viral filter.

6. Use a heat moisture exchanger device instead of tracheostomy collar during weaning to prevent virus spread or reinfection of patients.

7. Avoid changing the tracheostomy tube until viral load is as low as possible.

Conclusions

We acknowledge that these challenging times require extraordinary efforts. Maintaining the health and strength of our clinical workforce is critical to avoiding collapse of our health care system. However, the experience of our colleagues in Singapore and Hong Kong in protecting their health care workers is quite reassuring. By following carefully planned routines and procedures, we will be able to provide excellent care and help protect the safety and health of our colleagues.
